The Exterior Calculus

# Description

Provides functionality for working with tensors, alternating forms, wedge products, Stokes's theorem, and related concepts from the exterior calculus. Uses 'disordR' discipline (Hankin, 2022, <doi:10.48550/ARXIV.2210.03856>). The canonical reference would be M. Spivak (1965, ISBN:0-8053-9021-9) "Calculus on Manifolds". To cite the package in publications please use Hankin (2022) <doi:10.48550/ARXIV.2210.17008>.

#### **Details**

#### The DESCRIPTION file:

Package: stokes Type: Package

Title: The Exterior Calculus

Version: 1.1-6

Depends: spray (>= 1.0-21), R (>= 3.5.0)

Suggests: knitr, Deriv, testthat, markdown, rmarkdown, emulator

VignetteBuilder: knitr

Imports: permutations (>= 1.0-4), partitions, methods, mathjaxr, disordR (>= 0.0-8)

Authors@R: person(given=c("Robin", "K. S."), family="Hankin", role = c("aut", "cre"), email="hankin.robin@gma

Maintainer: Robin K. S. Hankin <a href="mailto:knakin.robin@gmail.com">hankin.robin@gmail.com</a>

Description: Provides functionality for working with tensors, alternating forms, wedge products, Stokes's theorem,

License: GPL-2

Generally in the package, arguments that are k-forms are denoted K, k-tensors by U, and spray objects by S. Multilinear maps (which may be either k-forms or k-tensors) are denoted by M.

4 Alt

#### See Also

spray

```
## Some k-tensors:
U1 <- as.ktensor(matrix(1:15,5,3))</pre>
U2 <- as.ktensor(cbind(1:3,2:4),1:3)
## Coerce a tensor to functional form, here mapping V^3 -> R (here V=R^15):
as.function(U1)(matrix(rnorm(45),15,3))
## Tensor product is tensorprod() or %X%:
U1 %X% U2
## A k-form is an alternating k-tensor:
K1 <- as.kform(cbind(1:5,2:6),rnorm(5))</pre>
K2 <- kform_general(3:6,2,1:6)</pre>
K3 <- rform(9,3,9,runif(9))</pre>
## The distributive law is true
(K1 + K2) ^{\wedge} K3 == K1 ^{\wedge} K3 + K2 ^{\wedge} K3 # TRUE to numerical precision
## Wedge product is associative (non-trivial):
(K1 ^ K2) ^ K3
K1 ^ (K2 ^ K3)
## k-forms can be coerced to a function and wedge product:
f <- as.function(K1 ^ K2 ^ K3)</pre>
## E is a a random point in V^k:
E <- matrix(rnorm(63),9,7)</pre>
## f() is alternating:
f(E)
f(E[,7:1])
## The package blurs the distinction between symbolic and numeric computing:
dx <- as.kform(1)</pre>
dy <- as.kform(2)</pre>
dz <- as.kform(3)</pre>
dx ^ dy ^ dz
K3 ^ dx ^ dy ^ dz
```

Alt 5

#### **Description**

Converts a k-tensor to alternating form

## Usage

Alt(S,give\_kform)

#### **Arguments**

S A multilinear form, an object of class ktensor

give\_kform Boolean, with default FALSE meaning to return an alternating k-tensor [that is, an object of class ktensor that happens to be alternating] and TRUE meaning to

return a k-form [that is, an object of class kform]

#### **Details**

Given a k-tensor T, we have

$$Alt(T)(v_1, \dots, v_k) = \frac{1}{k!} \sum_{\sigma \in S_k} sgn(\sigma) \cdot T(v_{\sigma(1)}, \dots, v_{\sigma(k)})$$

Thus for example if k = 3:

$$Alt(T)(v_1, v_2, v_3) = \frac{1}{6} \begin{pmatrix} +T(v_1, v_2, v_3) & -T(v_1, v_3, v_2) \\ -T(v_2, v_1, v_3) & +T(v_2, v_3, v_1) \\ +T(v_3, v_1, v_2) & -T(v_3, v_2, v_1) \end{pmatrix}$$

and it is reasonably easy to see that  $\mathrm{Alt}(T)$  is alternating, in the sense that

$$Alt(T) (v_1, \dots, v_i, \dots, v_i, \dots, v_k) = -Alt(T) (v_1, \dots, v_i, \dots, v_i, \dots, v_k)$$

Function Alt() is intended to take and return an object of class ktensor; but if given a kform object, it just returns its argument unchanged.

A short vignette is provided with the package: type vignette("Alt") at the commandline.

## Value

Returns an alternating k-tensor. To work with k-forms, which are a much more efficient representation of alternating tensors, use as .kform().

## Author(s)

Robin K. S. Hankin

## See Also

kform

6 as.1form

#### **Examples**

```
(X <- ktensor(spray(rbind(1:3),6)))
Alt(X)
Alt(X,give_kform=TRUE)

S <- as.ktensor(expand.grid(1:3,1:3),rnorm(9))
S
Alt(S)

issmall(Alt(S) - Alt(Alt(S))) # should be TRUE; Alt() is idempotent
a <- rtensor()
V <- matrix(rnorm(21),ncol=3)
LHS <- as.function(Alt(a))(V)
RHS <- as.function(Alt(a,give_kform=TRUE))(V)
c(LHS=LHS,RHS=RHS,diff=LHS-RHS)</pre>
```

as.1form

Coerce vectors to 1-forms

# Description

Given a vector, return the corresponding 1-form; the exterior derivative of a 0-form (that is, a scalar function). Function grad() is a synonym.

## Usage

```
as.1form(v)
grad(v)
```

## **Arguments**

٧

A vector with element i being  $\partial f/\partial x_i$ 

## **Details**

The exterior derivative of a k-form  $\phi$  is a (k+1)-form  $d\phi$  given by

$$\mathbf{d}\phi\left(P_{\mathbf{x}}\left(\mathbf{v}_{i},\ldots,\mathbf{v}_{k+1}\right)\right) = \lim_{h \to 0} \frac{1}{h^{k+1}} \int_{\partial P_{\mathbf{x}}\left(h\mathbf{v}_{1},\ldots,h\mathbf{v}_{k+1}\right)} \phi$$

We can use the facts that

$$\mathbf{d}\left(f\,dx_{i_1}\wedge\cdots\wedge dx_{i_k}\right) = \mathbf{d}f\wedge dx_{i_1}\wedge\cdots\wedge dx_{i_k}$$

and

$$\mathbf{d}f = \sum_{j=1}^{n} (D_j f) \ dx_j$$

to calculate differentials of general k-forms. Specifically, if

coeffs 7

$$\phi = \sum_{1 \le i_i < \dots < i_k \le n} a_{i_1 \dots i_k} dx_{i_1} \wedge \dots \wedge dx_{i_k}$$

then

$$\mathbf{d}\phi = \sum_{1 \le i_i < \dots < i_k \le n} \left[ \sum_{j=1}^n D_j a_{i_1 \dots i_k} dx_j \right] \wedge dx_{i_1} \wedge \dots \wedge dx_{i_k}.$$

The entry in square brackets is given by grad(). See the examples for appropriate R idiom.

#### Value

A one-form

## Author(s)

Robin K. S. Hankin

#### See Also

kform

## **Examples**

```
as.1form(1:9) # note ordering of terms as.1form(rnorm(20)) grad(c(4,7)) ^ grad(1:4)
```

coeffs

Extract and manipulate coefficients

## **Description**

Extract and manipulate coefficients of ktensor and kform objects; this using the methods of the **spray** package.

## **Details**

To see the coefficients of a kform or ktensor object, use coeffs(), which returns a disord object (this is actually spray::coeffs()). Replacement methods also use the methods of the **spray** package.

#### Author(s)

Robin K. S. Hankin

8 consolidate

#### **Examples**

```
(a <- kform_general(5,2,1:10))
coeffs(a) # a disord object
coeffs(a)[coeffs(a)%%2==1] <- 100 # replace every odd coeff with 100
a
coeffs(a*0)</pre>
```

consolidate

Various low-level helper functions

# Description

Various low-level helper functions used in Alt() and kform()

# Usage

```
consolidate(S)
kill_trivial_rows(S)
include_perms(S)
kform_to_ktensor(S)
```

## **Arguments**

S

Object of class spray

#### **Details**

Low-level helper functions.

- Function consolidate() takes a spray object, and combines any rows that are identical up to a permutation, respecting the sign of the permutation
- Function kill\_trivial\_rows() takes a spray object and deletes any rows with a repeated entry (which have k-forms identically zero)
- Function include\_perms() replaces each row of a spray object with all its permutations, respecting the sign of the permutation
- Function ktensor\_to\_kform() coerces a k-form to a k-tensor

## Value

The functions documented here all return a spray object.

## Author(s)

Robin K. S. Hankin

## See Also

```
ktensor,kform,Alt
```

contract 9

#### **Examples**

```
(S <- spray(matrix(c(1,1,2,2,1,3,3,1,3,5),ncol=2,byrow=TRUE),1:5))
kill_trivial_rows(S)  # (rows 1 and 3 killed, repeated entries)
consolidate(S)  # (merges rows 2 and 4)
include_perms(S)  # returns a spray object, not alternating tensor.</pre>
```

contract

Contractions of k-forms

## Description

A contraction is a natural linear map from k-forms to k-1-forms.

# Usage

```
contract(K,v,lose=TRUE)
contract_elementary(o,v)
```

# Arguments

K	A $k$ -form
0	Integer-valued vector corresponding to one row of an index matrix
lose	Boolean, with default TRUE meaning to coerce a $0$ -form to a scalar and FALSE meaning to return the formal $0$ -form
v	A vector; in function contract(), if a matrix, interpret each column as a vector to contract with

## **Details**

Given a k-form  $\phi$  and a vector  $\mathbf{v}$ , the contraction  $\phi_{\mathbf{v}}$  of  $\phi$  and  $\mathbf{v}$  is a k-1-form with

$$\phi_{\mathbf{v}}\left(\mathbf{v}^{1},\ldots,\mathbf{v}^{k-1}\right)=\phi\left(\mathbf{v},\mathbf{v}^{1},\ldots,\mathbf{v}^{k-1}\right)$$

provided k>1; if k=1 we specify  $\phi_{\mathbf{v}}=\phi(\mathbf{v}).$ 

Function contract\_elementary() is a low-level helper function that translates elementary k-forms with coefficient 1 (in the form of an integer vector corresponding to one row of an index matrix) into its contraction with  $\mathbf{v}$ .

There is an extensive vignette in the package, vignette("contract").

## Value

Returns an object of class kform.

## Author(s)

Robin K. S. Hankin

10 dovs

#### References

Steven H. Weintraub 2014. "Differential forms: theory and practice", Elsevier (Definition 2.2.23, chapter 2, page 77).

```
wedge,lose
```

## **Examples**

```
contract(as.kform(1:5),1:8)
contract(as.kform(1),3) # 0-form

## Now some verification [takes ~10s to run]:
#o <- kform(spray(t(replicate(2, sample(9,4))), runif(2)))
#V <- matrix(rnorm(36),ncol=4)
#jj <- c(
# as.function(o)(V),
# as.function(contract(o,V[,1,drop=TRUE]))(V[,-1]), # scalar
# as.function(contract(o,V[,1:2]))(V[,-(1:2),drop=FALSE]),
# as.function(contract(o,V[,1:3]))(V[,-(1:3),drop=FALSE]),
# as.function(contract(o,V[,1:4],lose=FALSE))(V[,-(1:4),drop=FALSE])
#)

#print(jj)
#max(jj) - min(jj) # zero to numerical precision</pre>
```

dovs

Dimension of the underlying vector space

## **Description**

A k-form  $\omega \in \Lambda^k(V)$  maps  $V^k$  to the reals, where  $V = \mathcal{R}^n$ . Function dovs() returns n, the dimensionality of the underlying vector space. The function itself is almost trivial, returning the maximum of the index matrix.

Special dispensation is given for zero-forms and zero tensors, which return zero.

#### Usage

```
dovs(K)
```

## **Arguments**

K A k-formor k-tensor

## Value

Returns a non-negative integer

dx 11

#### Author(s)

Robin K. S. Hankin

# **Examples**

```
dovs(rform())
table(replicate(20,dovs(rform(3))))
```

dx

Elementary forms

## **Description**

Objects dx, dy and dz are the three elementary one-forms on three-dimensional space. These objects can be generated by running script 'vignettes/dx.Rmd', which includes some further discussion and technical documentation and creates file 'dx.rda' which resides in the data/ directory.

The default print method is a little opaque for these objects. To print them more intuitively, use

```
options(kform_symbolic_print = "dx")
which is documented at print.Rd.
```

## Usage

data(dx)

## **Details**

See the vignette for an extended discussion.

```

hodge

## **Examples**

```
dx
hodge(dx)
hodge(dx,3)

dx  # default print method, not particularly intelligible
options(kform_symbolic_print = 'dx')  # shows dx dy dz
dx
dx^dz
hodge(dx,3)

options(kform_symbolic_print = NULL)  # revert to default
```

hodge

Hodge star operator

# Description

Given a k-form, return its Hodge dual

# Usage

```
hodge(K, n=dovs(K), g, lose=TRUE)
```

# **Arguments**

K	Object of class kform
n	Dimensionality of space, defaulting the the largest element of the index
g	Diagonal of the metric tensor, with missing default being the standard metric of the identity matrix. Currently, only entries of $\pm 1$ are accepted
lose	Boolean, with default TRUE meaning to coerce to a scalar if appropriate

## Value

Given a k-form, in an n-dimensional space, return a (n-k)-form.

#### Note

Most authors write the Hodge dual of  $\psi$  as  $*\psi$  or  $*\psi$ , but Weintraub uses  $\psi*$ .

# Author(s)

Robin K. S. Hankin

# See Also

wedge

inner 13

#### **Examples**

```
(o <- kform_general(5,2,1:10))
hodge(o)

Faraday <- kform_general(4,2,runif(6)) # Faraday electromagnetic tensor
minsk <- c(-1,1,1,1) # Minkowski metric
hodge(Faraday,g=minsk)
Faraday==Faraday|>hodge(g=minsk)|>hodge(g=minsk)|>hodge(g=minsk)|>hodge(g=minsk)|>hodge(dx,3) == dy^dz

## Some edge-cases:
hodge(scalar(1),2)
hodge(zero(5),9)
hodge(volume(5))
hodge(volume(5)),lose=TRUE)
hodge(scalar(7),n=9)
```

inner

Inner product operator

## **Description**

The inner product

## Usage

inner(M)

# **Arguments**

М

square matrix

#### **Details**

The inner product of two vectors  $\mathbf{x}$  and  $\mathbf{y}$  is usually written  $\langle \mathbf{x}, \mathbf{y} \rangle$  or  $\mathbf{x} \cdot \mathbf{y}$ , but the most general form would be  $\mathbf{x}^T M \mathbf{y}$  where M is a matrix. Noting that inner products are multilinear, that is  $\langle \mathbf{x}, a\mathbf{y} + b\mathbf{z} \rangle = a \langle \mathbf{x}, \mathbf{y} \rangle + b \langle \mathbf{x}, \mathbf{z} \rangle$  and  $\langle a\mathbf{x} + b\mathbf{y}, \mathbf{z} \rangle = a \langle \mathbf{x}, \mathbf{z} \rangle + b \langle \mathbf{y}, \mathbf{z} \rangle$ , we see that the inner product is indeed a multilinear map, that is, a tensor.

Given a square matrix M, function inner(M) returns the 2-form that maps  $\mathbf{x}, \mathbf{y}$  to  $\mathbf{x}^T M \mathbf{y}$ . Non-square matrices are effectively padded with zeros.

A short vignette is provided with the package: type vignette("inner") at the commandline.

## Value

Returns a k-tensor, an inner product

14 issmall

#### Author(s)

Robin K. S. Hankin

## See Also

kform

as.kform(inner(matrix(1:9,3,3))) # Same thing coerced to a kform

f <- as.function(inner(diag(7)))
X <- matrix(rnorm(14),ncol=2) # random element of (R^7)^2
f(X) - sum(X[,1]*X[,2]) # zero to numerical precision

## verify positive-definiteness:
g <- as.function(inner(crossprod(matrix(rnorm(56),8,7))))
stopifnot(g(kronecker(rnorm(7),t(c(1,1))))>0)
```

issmall

Is a form zero to within numerical precision?

# Description

Given a k-form, return TRUE if it is "small"

# Usage

```
issmall(M, tol=1e-8)
```

# Arguments

M Object of class kform or ktensor tol Small tolerance, defaulting to 1e-8

#### Value

Returns a logical

# Author(s)

Robin K. S. Hankin

keep 15

#### **Examples**

```
o <- kform_general(3,2,runif(3))
M <- matrix(rnorm(9),3,3)

discrepancy <- o - pullback(pullback(o,M),solve(M))

discrepancy # print method might imply coefficents are zeros
issmall(discrepancy) # should be TRUE
is.zero(discrepancy) # might be FALSE</pre>
```

keep

Keep or drop variables

## **Description**

Keep or drop variables

## Usage

```
keep(K, yes)
discard(K, no)
```

## **Arguments**

K Object of class kform

yes, no Specification of dimensions to either keep (yes) or discard (no), coerced to a free

object

#### **Details**

Function keep(omega, yes) keeps the terms specified and discard(omega, no) discards the terms specified. It is not clear to me what these functions mean from a mathematical perspective.

#### Value

The functions documented here all return a kform object.

## Author(s)

```
Robin K. S. Hankin
```

## See Also

lose

```
(o <- kform_general(7,3,seq_len(choose(7,3)))) keep(o,1:4)  # keeps only terms with dimensions 1-4 discard(o,1:2)  # loses any term with a "1" in the index
```

16 kform

#### **Description**

Functionality for dealing with k-forms

#### Usage

```
kform(S)
as.kform(M,coeffs,lose=TRUE)
kform_basis(n, k)
kform_general(W,k,coeffs,lose=TRUE)
is.kform(x)
d(i)
## S3 method for class 'kform'
as.function(x,...)
```

## **Arguments**

n	Dimension of the vector space $V = \mathbb{R}^n$
i	Integer
k	A $k$ -form maps $V^k$ to $R$
W	Integer vector of dimensions
M,coeffs	Index matrix and coefficients for a $k$ -form
S	Object of class spray
lose	Boolean, with default TRUE meaning to coerce a $0\text{-}\mathrm{form}$ to a scalar and FALSE meaning to return the formal $0\text{-}\mathrm{form}$
x	Object of class kform
	Further arguments, currently ignored

#### **Details**

A k-form is an alternating k-tensor. In the **stokes** package, k-forms are represented as sparse arrays (spray objects), but with a class of c("kform", "spray"). The constructor function kform() takes a spray object and returns a kform object: it ensures that rows of the index matrix are strictly nonnegative integers, have no repeated entries, and are strictly increasing. Function as.kform() is more user-friendly.

- kform() is the constructor function. It takes a spray object and returns a kform.
- as.kform() also returns a kform but is a bit more user-friendly than kform().
- kform\_basis() is a low-level helper function that returns a matrix whose rows constitute a basis for the vector space  $\Lambda^k(\mathbb{R}^n)$  of k-forms.
- kform\_general() returns a kform object with terms that span the space of alternating tensors.
- is.kform() returns TRUE if its argument is a kform object.
- d() is an easily-typed synonym for as .kform(). The idea is that d(1) = dx, d(2)=dy,  $d(5)=dx^5$ , etc. Also note that, for example,  $d(1:3)=dx^dy^dz$ , the volume form.

kform 17

Recall that a k-tensor is a multilinear map from  $V^k$  to the reals, where  $V = \mathbb{R}^n$  is a vector space. A multilinear k-tensor T is alternating if it satisfies

$$T(v_1,\ldots,v_i,\ldots,v_j,\ldots,v_k) = -T(v_1,\ldots,v_j,\ldots,v_i,\ldots,v_k)$$

In the package, an object of class kform is an efficient representation of an alternating tensor.

Function kform\_basis() is a low-level helper function that returns a matrix whose rows constitute a basis for the vector space  $\Lambda^k(\mathbb{R}^n)$  of k-forms:

$$\phi = \sum_{1 \le i_1 < \dots < i_k \le n} a_{i_1 \dots i_k} dx_{i_1} \wedge \dots \wedge dx_{i_k}$$

and indeed we have:

$$a_{i_1\dots i_k} = \phi\left(\mathbf{e}_{i_1},\dots,\mathbf{e}_{i_k}\right)$$

where  $e_j$ ,  $1 \le j \le k$  is a basis for V.

#### Value

All functions documented here return a kform object except as.function.kform(), which returns a function, and is.kform(), which returns a Boolean.

#### Note

Hubbard and Hubbard use the term "k-form", but Spivak does not.

```

18 kinner

kinner

Inner product of two kforms

## **Description**

Given two k-forms  $\alpha$  and  $\beta$ , return the inner product  $\langle \alpha, \beta \rangle$ . Here our underlying vector space V is  $\mathbb{R}^n$ .

The inner product is a symmetric bilinear form defined in two stages. First, we specify its behaviour on decomposable k-forms  $\alpha = \alpha_1 \wedge \cdots \wedge \alpha_k$  and  $\beta = \beta_1 \wedge \cdots \wedge \beta_k$  as

$$\langle \alpha, \beta \rangle = \det \left( \langle \alpha_i, \beta_j \rangle_{1 \le i, j \le n} \right)$$

and secondly, we extend to the whole of  $\Lambda^k(V)$  through linearity.

# Usage

kinner(o1,o2,M)

## **Arguments**

o1, o2 Objects of class kform

M Matrix

#### Value

Returns a real number

## Note

is.ktensor(x)
## S3 method for class 'ktensor'
as.function(x,...)
```

## **Arguments**

M, coeffs
 Matrix of indices and coefficients, as in spray(M, coeffs)
 Object of class spray
 Object of class ktensor
 Further arguments, currently ignored

#### **Details**

A k-tensor object S is a map from  $V^k$  to the reals R, where V is a vector space (here  $R^n$ ) that satisfies multilinearity:

$$S(v_1, \dots, av_i, \dots, v_k) = a \cdot S(v_1, \dots, v_i, \dots, v_k)$$

and

$$S(v_1, \dots, v_i + v_i', \dots, v_k) = S(v_1, \dots, v_i, \dots, x_v) + S(v_1, \dots, v_i', \dots, v_k).$$

Note that this is *not* equivalent to linearity over  $V^{nk}$  (see examples).

In the **stokes** package, k-tensors are represented as sparse arrays (spray objects), but with a class of c("ktensor", "spray"). This is a natural and efficient representation for tensors that takes advantage of sparsity using **spray** package features.

Function as.ktensor() will coerce a *k*-form to a *k*-tensor via kform\_to\_ktensor().

20 ktensor

#### Value

All functions documented here return a ktensor object except as.function.ktensor(), which returns a function.

```

Ops.kform 21

Ops.kform

Arithmetic Ops Group Methods for kform and ktensor objects

#### **Description**

Allows arithmetic operators to be used for k-forms and k-tensors such as addition, multiplication, etc., where defined.

# Usage

```
## $3 method for class 'kform'
Ops(e1, e2 = NULL)
## $3 method for class 'ktensor'
Ops(e1, e2 = NULL)
```

#### **Arguments**

e1,e2

Objects of class kform or ktensor

#### **Details**

The functions Ops.kform() and Ops.ktensor() pass unary and binary arithmetic operators ("+", "-", "\*", "/" and "^") to the appropriate specialist function by coercing to spray objects.

For wedge products of k-forms, use wedge() or %^% or ^; and for tensor products of k-tensors, use tensorprod() or %X%.

#### Value

All functions documented here return an object of class kform or ktensor.

#### Note

A plain asterisk, "\*" behaves differently for ktensors and kforms. Given two ktensors T1, T2, then "T1\*T2" will return the their tensor product. This on the grounds that the idiom has only one natural interpretation. But its use is discouraged (use %X% or tensorprod() instead). An asterisk can also be used to multiply a tensor by a scalar, as in T1\*5.

An asterisk cannot be used to multiply two kforms K1, K2, as in K1\*K2, which will always return an error. This on the grounds that it has no sensible interpretation in general and you probably meant to use a wedge product, K1^K2. Note that multiplication by scalars is acceptable, as in K1\*6. Further note that K1\*K2 returns an error even if one or both is a 0-form (or scalar), as in K1\*scalar(3). This behaviour may change in the future.

In the package the caret ("^") evaluates the wedge product; note that %^% is also acceptable. Powers simply do not make sense for alternating forms:  $S \%^{S} = S^{S}$  is zero identically. Here the caret is interpreted consistently as a wedge product, and if one of the factors is numeric it is interpreted as a zero-form (that is, a scalar). Thus  $S^{2} = \text{wedge}(S,2) = 2^{S} = S*2 = S*5$ , and indeed  $S^{n}=S*n$ . Caveat emptor! If S is a kform object, it is very tempting [but incorrect] to interpret "S^3" as something like "S to the power 3". See also the note at Ops.clifford in the **clifford** package.

Powers are not implemented for ktensors on the grounds that a ktensor to the power zero is not defined.

22 print.stokes

Note that one has to take care with order of operations, as package idiom is not quite associative if we mix  $^{\circ}$  with  $^{\circ}$ . For example, dx  $^{\circ}$  (6\*dy) is perfectly acceptable; but (dx  $^{\circ}$  6)\*dy) will return an error, as will the unbracketed form dx  $^{\circ}$  6 \* dy. In the second case we attempt to use an asterisk to multiply two k-forms, which triggers the error.

## Author(s)

Robin K. S. Hankin

#### **Examples**

```
## dx_1 ^ dx_2 + 6dx_5 ^ dx_6:
as.kform(1) ^ as.kform(2) + 6*as.kform(5) ^ as.kform(6)

k1 <- kform_general(4,2,rnorm(6))
k2 <- kform_general(4,2,rnorm(6))

E <- matrix(rnorm(8),4,2)
as.function(k1+k2)(E)

## verify linearity, here 2*k1 + 3*k2:
as.function(2*k1+3*k2)(E)-(2*as.function(k1)(E) + 3*as.function(k2)(E))
## should be small</pre>
```

print.stokes

Print methods for k-tensors and k-forms

# Description

Print methods for objects with options for printing in matrix form or multivariate polynomial form

## Usage

```
## S3 method for class 'kform'
print(x, ...)
## S3 method for class 'ktensor'
print(x, ...)
```

#### **Arguments**

```
x k-form or k-tensor ... Further arguments (currently ignored)
```

#### **Details**

The print method is designed to tell the user that an object is a tensor or a k-form. It prints a message to this effect (with special dispensation for zero tensors), then calls the spray print method.

## Value

Returns its argument invisibly.

print.stokes 23

#### Note

The print method asserts that its argument is a map from  $V^k$  to R with  $V=R^n$ . Here, n is the largest element in the index matrix. However, such a map naturally furnishes a map from  $(R^m)^k$  to R provided that  $m \geq n$  via the natural projection from  $R^n$  to  $R^m$ . Formally this would be  $(x_1,\ldots,x_n)\mapsto (x_1,\ldots,x_n,0,\ldots,0)\in R^m$ . In the case of the zero k-form or k-tensor, "n" is to be interpreted as "any  $n\geq 0$ ". See also dovs ().

By default, the print method uses the **spray** print methods, and as such respects the polyform option. However, setting polyform to TRUE can give misleading output, because **spray** interprets objects as multivariate polynomials not differential forms (and in particular uses the caret to signify powers).

It is much better to use options ktensor\_symbolic\_print or kform\_symbolic\_print instead. If these options are non-null, the print method uses as.symbolic() to give an alternate way of displaying k-tensors and k-forms. The generic non-null value would be "x" which gives output like "dx1 ^ dx2". However, it has two special values: set kform\_symbolic\_print to "dx" for output like "dx ^ dz" and "txyz" for output like "dt ^ dx", useful in relativistic physics with a Minkowski metric. See the examples.

More detail is given at symbolic.Rd and the dx vignette.

a</pre>
```

24 rform

rform	Random kforms and ktensors	

## **Description**

Random k-form objects and k-tensors, intended as quick "get you going" examples

# Usage

```
rform(terms=9,k=3,n=7,coeffs,ensure=TRUE)
rtensor(terms=9,k=3,n=7,coeffs)
```

# Arguments

terms	Number of distinct terms
k,n	A $k$ -form maps $V^k$ to $R$ , where $V = R^n$
coeffs	The coefficients of the form; if missing use seq_len(terms)
ensure	Boolean with default TRUE meaning to ensure that the dovs() of the returned value is in fact equal to n. If FALSE, sometimes the dovs() is strictly less than n because of random sampling

# **Details**

What you see is what you get, basically.

Note that argument terms is an upper bound, as the index matrix might contain repeats which are combined.

## Value

All functions documented here return an object of class kform or ktensor.

# Author(s)

Robin K. S. Hankin

```
rform()
rform() %^% rform()
rtensor() %X% rtensor()
rform() ^ dx
rform() ^ dx ^ dy
```

scalar 25

scalar

Scalars and losing attributes

#### **Description**

Scalars: 0-forms and 0-tensors

#### Usage

## **Arguments**

s A scalar value; a number

kform Boolean with default TRUE meaning to return a kform and FALSE meaning to

return a ktensor

M Object of class ktensor or kform

lose In function scalar(), Boolean with TRUE meaning to return a normal scalar,

and default FALSE meaning to return a formal 0-form or 0-tensor  $\,$ 

#### **Details**

A k-tensor (including k-forms) maps k vectors to a scalar. If k=0, then a 0-tensor maps no vectors to a scalar, that is, mapping nothing at all to a scalar, or what normal people would call a plain old scalar. Such forms are created by a couple of constructions in the package, specifically scalar(), kform\_general(1,0) and contract(). These functions take a lose argument that behaves much like the drop argument in base extraction. Functions '0form()' and '0tensor()' are wrappers for 'scalar()'.

Function lose() takes an object of class ktensor or kform and, if of arity zero, returns the coefficient.

Note that function kform() always returns a kform object, it never loses attributes.

There is a slight terminological problem. A k-form maps k vectors to the reals: so a 0-form maps k vectors to the reals. This is what anyone on the planet would call a scalar. Similarly, a 0-tensor maps k vectors to the reals, and so is a scalar. Mathematically, there is no difference between 0-forms and 0-tensors, but the package makes a distinction:

```
> scalar(5,kform=TRUE)
An alternating linear map from V^0 to R with V=R^0:
    val
= 5
> scalar(5,kform=FALSE)
A linear map from V^0 to R with V=R^0:
```

26 summary.stokes

```
val
= 5
```

Compare zero tensors and zero forms. A zero tensor maps  $V^k$  to the real number zero, and a zero form is an alternating tensor mapping  $V^k$  to zero (so a zero tensor is necessarily alternating). See zero.Rd.

#### Value

The functions documented here return an object of class kform or ktensor, except for is.scalar(), which returns a Boolean.

#### Author(s)

Robin K. S. Hankin

summary(a)
options(kform_symbolic_print = TRUE)
summary(a)
options(kform_symbolic_print = NULL) # restore default</pre>
```

symbolic

Symbolic form

## **Description**

Returns a character string representing k-tensor and k-form objects in symbolic form. Used by the print method if either option kform\_symbolic\_print or ktensor\_symbolic\_print is non-null.

### Usage

```
as.symbolic(M,symbols=letters,d="")
```

## **Arguments**

М	Object of class kform or ktensor; a map from $V^k$ to $R$ , where $V = R^n$
symbols	A character vector giving the names of the symbols
d	String specifying the appearance of the differential operator

#### **Details**

Spivak (p89), in archetypically terse writing, states:

A function f is considered to be a 0-form and  $f \cdot \omega$  is also written  $f \wedge \omega$ . If  $f \colon \mathcal{R}^n \longrightarrow \mathcal{R}$  is differentiable, then  $Df(p) \in \Lambda^1(\mathcal{R}^n)$ . By a minor modification we therefore obtain a 1-form df, defined by

$$df(p)(v_p) = Df(p)(v)$$

Let us consider in particular the 1-forms  $d\pi^i$ . It is customary to let  $x^i$  denote the function  $\pi^i$  (On  $\mathbb{R}^3$  we often denote  $x^1, x^2$ , and  $x^3$  by x, y, and z). This standard notation has obvious disadvantages but it allows many classical results to be expressed by formulas of equally classical appearance. Since  $dx^i(p)(v_p) = d\pi^i(p)(v_p) = D\pi^i(p)(v) = v^i$ , we see that  $dx^1(p), \ldots, dx^n(p)$  is just the dual basis to  $(e_1)_p, \ldots, (e_n)_p$ . Thus every k-form  $\omega$  can be written

28 tensorprod

$$\omega = \sum_{i_1 < \dots < i_k} \omega_{i_1, \dots, i_k} dx^{i_1} \wedge \dots \wedge dx^{i_k}.$$

Function as.symbolic() uses this format. For completeness, we add (p77) that k-tensors may be expressed in the form

$$\sum_{i_1,\ldots,i_k=1}^n a_{i_1,\ldots,i_k} \cdot \phi_{i_1} \otimes \cdots \otimes \phi_{i_k}.$$

and this form is used for k-tensors.

#### Value

Returns a "noquote" character string.

# Author(s)

Robin K. S. Hankin

#### See Also

```
print.stokes,dx
```

# **Examples**

```
(o <- kform_general(3,2,1:3))
as.symbolic(o,d="d",symbols=letters[23:26])
(a <- rform(n=50))
as.symbolic(a,symbols=state.abb)</pre>
```

tensorprod

Tensor products of k-tensors

## **Description**

Tensor products of k-tensors

# Usage

```
tensorprod(U, ...)
tensorprod2(U1,U2)
```

## **Arguments**

U, U1, U2 Object of class ktensor

... Further arguments, currently ignored

tensorprod 29

#### **Details**

Given a k-tensor S and an l-tensor T, we can form the tensor product  $S \otimes T$ , defined as

$$S \otimes T\left(v_1,\ldots,v_k,v_{k+1},\ldots,v_{k+l}\right) = S\left(v_1,\ldots v_k\right) \cdot T\left(v_{k+1},\ldots v_{k+l}\right).$$

Package idiom for this includes tensorprod(S,T) and S %X% T; note that the tensor product is not commutative. Function tensorprod() can take any number of arguments (the result is well-defined because the tensor product is associative); it uses tensorprod2() as a low-level helper function.

#### Value

The functions documented here all return a spray object.

#### Note

The binary form %X% uses uppercase X to avoid clashing with %x% which is the Kronecker product in base R.

30 transform

transform

*Linear transforms of k-forms* 

## **Description**

Given a k-form, express it in terms of linear combinations of the  $dx_i$ 

#### Usage

```
pullback(K,M)
stretch(K,d)
```

## **Arguments**

K Object of class kform

Matrix of transformation

d Numeric vector representing the diagonal elements of a diagonal matrix

#### **Details**

Function pullback() calculates the pullback of a function. A vignette is provided at 'pullback.Rmd'. Suppose we are given a two-form

$$\omega = \sum_{i < j} a_{ij} dx_i \wedge dx_j$$

and relationships

$$dx_i = \sum_r M_{ir} dy_r$$

then we would have

$$\omega = \sum_{i < j} a_{ij} \left( \sum_r M_{ir} dy_r \right) \wedge \left( \sum_r M_{jr} dy_r \right).$$

The general situation would be a k-form where we would have

$$\omega = \sum_{i_1 < \dots < i_k} a_{i_1 \dots i_k} dx_{i_1} \wedge \dots \wedge dx_{i_k}$$

giving

$$\omega = \sum_{i_1 < \dots < i_k} \left[ a_{i_1, \dots, i_k} \left( \sum_r M_{i_1 r} dy_r \right) \wedge \dots \wedge \left( \sum_r M_{i_k r} dy_r \right) \right].$$

The transform() function does all this but it is slow. I am not 100% sure that there isn't a much more efficient way to do such a transformation. There are a few tests in tests/testthat and a discussion in the stokes vignette.

Function stretch() carries out the same operation but for M a diagonal matrix. It is much faster than transform().

vector\_cross\_product 31

#### Value

The functions documented here return an object of class kform.

32 vector\_cross\_product

## **Description**

The vector cross product is defined in elementary school for pairs of vectors in  $\mathbb{R}^3$  as

$$\mathbf{u} \times \mathbf{v} = (u_2v_3 - u_3v_2, u_2v_3 - u_3v_2, u_2v_3 - u_3v_2).$$

However, this may easily be generalized to a product from n-1-tuples of vectors in  $\mathbb{R}^3$ . Vignette vector\_cross\_product gives a discussion.

## Usage

```
vector_cross_product(M)
```

## **Arguments**

М

Matrix with one more row than column; columns are interpreted as vectors

#### **Details**

See vignette vector\_cross\_product

#### Value

Returns a vector

#### Author(s)

Robin K. S. Hankin

#### See Also

cross

```
vector_cross_product(matrix(1:6,3,2))

M <- matrix(rnorm(30),6,5)

LHS <- hodge(as.1form(M[,1])^as.1form(M[,2])^as.1form(M[,3])^as.1form(M[,4])^as.1form(M[,5]))

RHS <- as.1form(vector_cross_product(M))

LHS-RHS  # zero to numerical precision

# Alternatively:
hodge(Reduce(`^`, sapply(seq_len(5), function(i){as.1form(M[,i])}, simplify=FALSE)))</pre>
```

volume 33

volume

The volume element

## **Description**

The volume element in n dimensions

## Usage

```
volume(n)
is.volume(K,n=dovs(K))
```

## **Arguments**

n Dimension of the space

K Object of class kform

# **Details**

Spivak phrases it well (theorem 4.6, page 82):

If V has dimension n, it follows that  $\Lambda^n(V)$  has dimension 1. Thus all alternating n-tensors on V are multiples of any non-zero one. Since the determinant is an example of such a member of  $\Lambda^n(V)$  it is not surprising to find it in the following theorem:

Let 
$$v_1, \ldots, v_n$$
 be a basis for  $V$  and let  $\omega \in \Lambda^n(V)$ . If  $w_i = \sum_{j=1}^n a_{ij}v_j$  then

$$\omega\left(w_{1},\ldots,w_{n}\right)=\det\left(a_{ij}\right)\cdot\omega\left(v_{1},\ldots v_{n}\right)$$

(see the examples for numerical verification of this).

Neither the zero k-form, nor scalars, are considered to be a volume element.

## Value

Function volume() returns an object of class kform; function is.volume() returns a Boolean.

#### Author(s)

Robin K. S. Hankin

```

34 wedge

## **Examples**

```
dx^dy^dz == volume(3)

p <- 1
for(i in 1:7){p <- p ^ as.kform(i)}
p
p == volume(7)  # should be TRUE

o <- volume(5)
M <- matrix(runif(25),5,5)
det(M) - as.function(o)(M)  # should be zero

is.volume(d(1) ^ d(2) ^ d(3) ^ d(4))
is.volume(d(1:9))</pre>
```

wedge

Wedge products

## **Description**

Wedge products of k-forms

# Usage

```
wedge2(K1,K2)
wedge(x, ...)
```

## **Arguments**

```
K1, K2, x, \dots k-forms
```

#### **Details**

Wedge product of k-forms.

## Value

The functions documented here return an object of class kform.

## Note

In general use, use wedge() or ^ or %^%, as documented under Ops. Function wedge() uses low-level helper function wedge2(), which takes only two arguments.

A short vignette is provided with the package: type vignette("wedge") at the commandline.

Robin K. S. Hankin

zap 35

#### See Also

0ps

## **Examples**

```
k1 <- as.kform(cbind(1:5,2:6),1:5)
k2 <- as.kform(cbind(5:7,6:8,7:9),1:3)
k3 <- kform_general(1:6,2)

a1 <- wedge2(k1,wedge2(k2,k3))
a2 <- wedge2(wedge2(k1,k2),k3)

is.zero(a1-a2)  # NB terms of a1, a2 in a different order!

# This is why wedge(k1,k2,k3) is well-defined. Can also use ^:
k1 ^ k2 ^ k3</pre>
```

zap

Zap small values in k-forms and k-tensors

# Description

Equivalent to zapsmall()

# Usage

```
zap(X)
## S3 method for class 'kform'
zap(X)
## S3 method for class 'ktensor'
zap(X)
```

# **Arguments**

Χ

Tensor or k-form to be zapped

#### **Details**

Given an object of class ktensor or kform, coefficients close to zero are 'zapped', i.e., replaced by '0', using base::zapsmall().

Note, zap() actually changes the numeric value, it is not just a print method.

## Value

Returns an object of the same class

#### Author(s)

Robin K. S. Hankin

```
S <- rform(7)
S == zap(S)</pre>
```

36 zero

zero

Zero tensors and zero forms

#### **Description**

Correct idiom for generating zero k-tensors and k-forms

#### Usage

```
zeroform(n)
zerotensor(n)
```

# Arguments

n

Arity of the k-form or k-tensor

## Value

Returns an object of class kform or ktensor.

#### Note

Idiom such as as.ktensor(rep(1,n),0) and as.kform(rep(1,5),0) and indeed as.kform(1:5,0) is incorrect as the arity of the tensor is lost.

A 0-form is not the same thing as a zero tensor. A 0-form maps  $V^0$  to the reals; a scalar. A zero tensor maps  $V^k$  to zero. Some discussion is given at scalar.Rd.
